

CANCER

The risk of developing hormone-dependent neoplasms (such as breast or endometrial cancer) is strongly linked to estrogen dominance and to defects in estrogen metabolism and elimination. The accumulation of reactive metabolites, combined with continuous exposure to xenoestrogens (plastics, parabens, pesticides) and oxidative stress, can cause damage to cellular DNA.

COMMON SYMPTOMS

- Presence of cysts, nodules, or fibroadenomas
- High exposure to endocrine disruptors (BPA, phthalates, microplastics)
- Inefficiency in hepatic detoxification processes (Phase 1 and Phase 2)
- Imbalance between DNA damage and repair mechanisms
